

Part D:

Reproducibility is essential within any field, however is very essential within financial data. This is because if your company is public, people like investors and the SEC will monitor what your company is doing as well as your finances and if the results and/or financial data you are outputting doesn't match they will investigate which could lead to fines and penalties.

Additionally, for any company finances must be submitted to the IRS for tax purposes and if there are errors or inconsistencies within the financial data then you could go under IRS audit and have potential jail time based on the scale and duration of the error.

Git tracks not only who has created and edited the file but also what purpose the edits had (comments on commits) as well as what changes were made during each commit. Additionally, it keeps track of branches (new features being added commonly) and merging of those branches to the main repository which can be helpful to track progression of development.

Finally, when working in a team it allows for version control and makes sure that all users are working on the most updated and active version, not accidentally working on an older version.
